Thank You for purchasing a Gorman-Rupp pump. Read this manual carefully to learn how to safely install and operate your pump. Failure to do so could result in personal injury or damage to the pump.

Because pump installations are seldom identical, this manual cannot possibly provide detailed instructions and precautions for every aspect of each specific application. Therefore, it is the responsibility of the owner/installer of the pump to ensure that applications not addressed in this manual are performed only after establishing that neither operator safety nor pump integrity are compromised by the installation. Pumps and related equipment must be installed and operated according to all national, local and industry standards.

If there are any questions regarding the pump or its application which are not covered in this manual or in other literature accompanying this unit, please contact your Gorman-Rupp distributor, or The Gorman-Rupp Company:

The Gorman-Rupp Company
P.O. Box 1217
Mansfield, Ohio 44901—1217
Phone: (419) 755—1011
or:
Gorman-Rupp of Canada Limited
70 Burwell Road
St. Thomas, Ontario N5P 3R7
Phone: (519) 631—2870

For information or technical assistance on the power source, contact the power source manufacturer’s local dealer or representative.

HAZARD AND INSTRUCTION DEFINITIONS

The following are used to alert maintenance personnel to procedures which require special attention, to those which could damage equipment, and to those which could be dangerous to personnel:

**DANGER!**

Immediate hazards which WILL result in severe personal injury or death. These instructions describe the procedure required and the injury which will result from failure to follow the procedure.

**WARNING!**

Hazards or unsafe practices which COULD result in severe personal injury or death. These instructions describe the procedure required and the injury which could result from failure to follow the procedure.

**CAUTION**

Hazards or unsafe practices which COULD result in minor personal injury or product or property damage. These instructions describe the requirements and the possible damage which could result from failure to follow the procedure.

**NOTE**

Instructions to aid in installation, operation, and maintenance or which clarify a procedure.
SAFETY - SECTION A

This information applies to Prime Aire® Series basic pumps. Gorman-Rupp has no control over or particular knowledge of the power source which will be used. Refer to the manual accompanying the power source before attempting to begin operation.

Because pump installations are seldom identical, this manual cannot possibly provide detailed instructions and precautions for each specific application. Therefore, it is the owner/installer’s responsibility to ensure that applications not addressed in this manual are performed only after establishing that neither operator safety nor pump integrity are compromised by the installation.

**WARNING!**

Before attempting to open or service the pump:

1. Familiarize yourself with this manual.
2. Disconnect or lock out the power source to ensure that the pump will remain inoperative.
3. Allow the pump to completely cool if overheated.
4. Check the temperature and make sure the pump is cool before opening any covers, plates, or plugs.
5. Close the suction and discharge valves.
6. Vent the pump slowly and cautiously.
7. Drain the pump.

**WARNING!**

This pump is designed to handle most non-volatile, non-flammable liquids containing specified entrained solids. Do not attempt to pump volatile, corrosive, or flammable liquids which may damage the pump or endanger personnel as a result of pump failure.

**WARNING!**

Death or serious personal injury and damage to the pump or components can occur if proper lifting procedures are not observed. Make certain that hoists, chains, slings or cables are in good working condition and of sufficient capacity and that they are positioned so that loads will be balanced and the pump or components will not be damaged when lifting. Suction and discharge hoses and piping must be removed from the pump before lifting. Lift the pump or component only as high as necessary and keep personnel away from suspended objects.

**WARNING!**

After the pump has been installed, make certain that the pump and all piping or hose connections are tight, properly supported and secure before operation.

**WARNING!**

Do not operate the pump against a closed discharge valve. If operated against a closed discharge valve, pump components will deteriorate, and the liquid could come to a boil, build pressure, and cause the pump casing to rupture or explode. Momentary closure of a discharge valve is acceptable only
when required for startup or shutdown procedures.

**WARNING!**

Do not operate the pump without the guards in place over the rotating parts. Exposed rotating parts can catch clothing, fingers, or tools, causing severe injury to personnel.

**WARNING!**

Do not remove plates, covers, gauges, pipe plugs, or fittings from an overheated pump. Vapor pressure within the pump can cause parts being disengaged to be ejected with great force. Allow the pump to cool completely before servicing.

**WARNING!**

This pump may be used to handle materials which could cause illness through direct exposure or emitted fumes. Wear adequate protective clothing when working on the pump or piping.

**CAUTION**

Pumps and related equipment must be installed and operated according to all national, local and industry standards.
Review all SAFETY information in Section A.

Since pump installations are seldom identical, this section offers only general recommendations and practices required to inspect, position, and arrange the pump and piping.

Most of the information pertains to a standard static lift application where the pump is positioned above the free level of liquid to be pumped.

If installed in a flooded suction application where the liquid is supplied to the pump under pressure, some of the information such as mounting, line configuration, and priming must be tailored to the specific application. Since the pressure supplied to the pump is critical to performance and safety, be sure to limit the incoming pressure to 50% of the maximum permissible operating pressure as shown on the pump performance curve.

For further assistance, contact your Gorman-Rupp distributor or the Gorman-Rupp Company.

PREINSTALLATION INSPECTION

The pump assembly was inspected and tested before shipment from the factory. Before installation, inspect the pump for damage which may have occurred during shipment. Check as follows:

a. Inspect the pump for cracks, dents, damaged threads, and other obvious damage.

b. Check for and tighten loose attaching hardware. Since gaskets tend to shrink after drying, check for loose hardware at mating surfaces.

c. Carefully read all warnings and cautions contained in this manual or affixed to the pump, and perform all duties indicated. Note the direction of rotation indicated on the pump. Check that the pump shaft rotates counterclockwise when facing the impeller.

d. Check levels and lubricate as necessary. Refer to LUBRICATION in the MAINTENANCE AND REPAIR section of this manual and perform duties as instructed.

e. If the pump and power source have been stored for more than 12 months, some of the components or lubricants may have exceeded their maximum shelf life. These must be inspected or replaced to ensure maximum pump service.

If the maximum shelf life has been exceeded, or if anything appears to be abnormal, contact your Gorman-Rupp distributor or the factory to determine the repair or updating policy. Do not put the pump into service until appropriate action has been taken.

POSITIONING PUMP

Lifting

Death or serious personal injury and damage to the pump or components can occur if proper lifting procedures are not observed. Make certain that hoists, chains, slings or cables are in good working condition and of sufficient capacity and that they are positioned so that loads will be balanced and the pump or components will not be damaged when lifting. Suction and discharge hoses and piping must be removed from the pump before lifting. Lift
the pump or component only as high as
necessary and keep personnel away
from suspended objects.

Pump unit weights will vary depending on the
mounting and drive provided. Check the shipping
tag on the unit packaging for the actual weight, and
use lifting equipment with appropriate capacity.
Drain the pump and remove all customer-installed
equipment such as suction and discharge hoses
or piping before attempting to lift existing, installed
units.

Mounting

Locate the pump in an accessible place as close as
practical to the liquid being pumped. Level mount­
ing is essential for proper operation.

The pump may have to be supported or shimmed
to provide for level operation or to eliminate vibra­
tion.

SUCTION AND DISCHARGE PIPING

Pump performance is adversely effected by in­
creased suction lift, discharge elevation, and fric­
tion losses. See the performance curve and oper­
ating range shown on Page E-1 to be sure your
overall application allows pump to operate within
the safe operation range.

Materials

Either pipe or hose maybe used for suction and
discharge lines; however, the materials must be
compatible with the liquid being pumped. If hose is
used in suction lines, it must be the rigid-wall, rein­
forced type to prevent collapse under suction. Us­
ing piping couplings in suction lines is not recom­
mended.

Line Configuration

Keep suction and discharge lines as straight as
possible to minimize friction losses. Make mini­
mum use of elbows and fittings, which substan­
tially increase friction loss. If elbows are necessary,
use the long-radius type to minimize friction loss.

Connections to Pump

Before tightening a connecting flange, align it ex­
actly with the pump port. Never pull a pipe line into
place by tightening the flange bolts and/or cou­
plings.

Lines near the pump must be independently sup­
ported to avoid strain on the pump which could
cause excessive vibration, decreased bearing life,
and increased shaft and seal wear. If hose-type lines are used, they should have adequate support
to secure them when filled with liquid and under
pressure.

Gauges

Most pumps are drilled and tapped for installing
discharge pressure and vacuum suction gauges. If
these gauges are desired for pumps that are not
tapped, drill and tap the suction and discharge
lines not less than 18 inches (457.2 mm) from the
suction and discharge ports and install the lines.
Installation closer to the pump may result in erratic
readings.

SUCTION LINES

To avoid air pockets which could affect pump prim­
ing, the suction line must be as short and direct as
possible. When operation involves a suction lift, the
line must always slope upward to the pump from
the source of the liquid being pumped; if the line
slopes down to the pump at any point along the
suction run, air pockets will be created.

Fittings

Suction lines should be the same size as the pump
inlet. If reducers are used in suction lines, they
should be the eccentric type, and should be in­
stalled with the flat part of the reducers uppermost

Strainers

If a strainer is furnished with the pump, be certain
to use it; any spherical solids which pass through a
If a strainer is not furnished with the pump, but is installed by the pump user, make certain that the total area of the openings in the strainer is at least three or four times the cross section of the suction line, and that the openings will not permit passage of solids larger than the solids handling capability of the pump.

This pump is designed to handle up to 1/2-inch (12.7 mm) diameter spherical solids.

Sealing

Since even a slight leak will affect priming, head, and capacity, especially when operating with a high suction lift, all connections in the suction line should be sealed with pipe dope to ensure an air-tight seal. Follow the sealant manufacturer’s recommendations when selecting and applying the pipe dope. The pipe dope should be compatible with the liquid being pumped.

Suction Lines In Sumps

If a single suction line is installed in a sump, it should be positioned away from the wall of the sump at a distance equal to 1 1/2 times the diameter of the suction line.

If there is a liquid flow from an open pipe into the sump, the flow should be kept away from the suction inlet because the inflow will carry air down into the sump, and air entering the suction line will reduce pump efficiency.

If it is necessary to position inflow close to the suction inlet, install a baffle between the inflow and the suction inlet at a distance 1 1/2 times the diameter of the suction pipe. The baffle will allow entrained air to escape from the liquid before it is drawn into the suction inlet.

If two suction lines are installed in a single sump, the flow paths may interact, reducing the efficiency of one or both pumps. To avoid this, position the suction inlets so that they are separated by a distance equal to at least 3 times the diameter of the suction pipe.

Suction Line Positioning

The depth of submergence of the suction line is critical to efficient pump operation. Figure 2 shows recommended minimum submergence vs. velocity.

NOTE

The pipe submergence required may be reduced by installing a standard pipe increaser fitting at the end of the suction line. The larger opening size will reduce the inlet velocity. Calculate the required submergence using the following formula based on the increased opening size (area or diameter).
DISCHARGE LINES

Siphoning

Do not terminate the discharge line at a level lower than that of the liquid being pumped unless a siphon breaker is used in the line. Otherwise, a siphoning action causing damage to the pump could result.

Valves

This pump is designed with a check valve in the discharge line.

If a throttling valve is desired in the discharge line, use a valve as large as the largest pipe to minimize friction losses. Never install a throttling valve in a suction line.

With high discharge heads, it is recommended that a throttling valve and a system check valve be installed in the discharge line to protect the pump from excessive shock pressure and reverse rotation when it is stopped.

CAUTION

If the application involves a high discharge head, gradually close the discharge throttling valve before stopping the pump.

ALIGNMENT

The alignment of the pump and its power source is critical for trouble-free mechanical operation. In either a flexible coupling or V-belt driven system, the driver and pump must be mounted so that their shafts are aligned with and parallel to each other. It is imperative that alignment be checked after the pump and piping are installed, and before operation.

NOTE

Check Rotation, Section C, before final alignment of the pump.

When mounted at the Gorman-Rupp factory, driver and pump are aligned before shipment. Misalignment will occur in transit and handling. Pumps
must be checked and realigned before operation. Before checking alignment, tighten the foundation bolts. The pump casing feet and/or pedestal feet, and the driver mounting bolts should also be tightly secured.

**WARNING!**

When checking alignment, disconnect the power source to ensure that the pump will remain inoperative.

**CAUTION**

Adjusting the alignment in one direction may alter the alignment in another direction. Check each procedure after altering alignment.

**Coupled Drives**

When using couplings, the axis of the power source must be aligned to the axis of the pump shaft in both the horizontal and vertical planes. Most couplings require a specific gap or clearance between the driving and the driven shafts. Refer to the coupling manufacturer’s service literature.

Align spider insert type couplings by using calipers to measure the dimensions on the circumference of the outer ends of the coupling hub every 90°. The coupling is in alignment when the hub ends are the same distance apart at all points (see Figure 2).

**Figure 2. Aligning Spider-Type Couplings**

**Figure 3. Aligning Non-Spider Type Couplings**

Align non-spider type couplings by using a feeler gauge or taper gauge between the coupling halves every 90°. The coupling is in alignment when the hubs are the same distance apart at all points (see Figure 3).

Check parallel adjustment by laying a straightedge across both coupling rims at the top, bottom, and side. When the straightedge rests evenly on both halves of the coupling, the coupling is in horizontal parallel alignment. If the coupling is misaligned, use a feeler gauge between the coupling and the straightedge to measure the amount of misalignment.

**Drive Belts**

When using drive belts, the power source and the pump must be parallel. Use a straightedge along the sides of the pulleys to ensure that the pulleys are properly aligned (see Figure 4). In drive systems using two or more belts, make certain that the belts are a matched set; unmatched sets will cause accelerated belt wear.

**Figure 4. Alignment of V-Belt Driven Pumps**
Tighten the belts in accordance with the belt manufacturer’s instructions. If the belts are too loose, they will slip; if the belts are too tight, there will be excessive power loss and possible bearing failure. Select pulleys that will match the proper speed ratio; overspeeding the pump may damage both pump and power source.

**DANGER!**

Do not operate the pump without the guard in place over the rotating parts. Exposed rotating parts can catch clothing, fingers, or tools, causing severe injury to personnel.

---

**DRIVE BELT TENSIONING**

**General Rules of Tensioning**

For new drive belts, check the tension after 5, 20 and 50 hours of operation and re-tension as required (see the following procedure for measuring belt tension). Thereafter, check and re-tension if required monthly or at 500 hour intervals, whichever comes first.

Ideal drive belt tension is the *lowest* tension at which the belt will not slip under peak load conditions. Do not over-tension drive belts. Over-tensioning will shorten both drive belt and bearing life. Under-tensioning will cause belt slippage. Always keep belts free from dirt, grease, oil and other foreign material which may cause slippage.
OPERATION — SECTION C

Review all SAFETY information in Section A.

Follow the instructions on all tags, labels and decals attached to the pump.

WARNING!

This pump is designed to handle most non-volatile, non-flammable liquids containing specified entrained solids. Do not attempt to pump volatile, corrosive, or flammable liquids which may damage the pump or endanger personnel as a result of pump failure.

CAUTION

Pump speed and operating condition points must be within the continuous performance range shown on the performance curve in Section E on page E-1.

PRIMING

Install the pump and piping as described in INSTALLATION. Make sure that the piping connections are tight, and that the pump is securely mounted. Check that the pump is properly lubricated (see LUBRICATION in MAINTENANCE AND REPAIR).

The pump will begin to prime upon startup. The air in the suction line will be discharged from the eductor discharge line. Complete priming is indicated by a positive discharge pressure reading.

If full priming is not achieved, the discharge check valve may be malfunctioning. If this occurs, shut down the pump and consult Maintenance and Repair, Section E for further details.

STARTING

Consult the operations manual furnished with the power source.

Rotation

The correct direction of pump rotation is counterclockwise when facing the impeller. The pump could be damaged and performance adversely affected by incorrect rotation. If pump performance is not within the specified limits (see the curve on page E-1), check the direction of power source rotation before further troubleshooting.

If an electric motor is used to drive the pump, remove V-belts, couplings, or otherwise disconnect the pump from the motor before checking motor rotation. Operate the motor independently while observing the direction of the motor shaft, or cooling fan.

If rotation is incorrect on a three-phase motor, have a qualified electrician interchange any two of the three phase wires to change direction. If rotation is incorrect on a single-phase motor, consult the literature supplied with the motor for specific instructions.

Priming

The pump will begin to prime upon startup. The air in the suction line will be discharged from the eductor discharge line. Complete priming is indicated by a positive discharge pressure reading.

If full priming is not achieved, the discharge check valve may be malfunctioning. If this occurs, shut down the pump and consult the separate Maintenance and Repair manual for further details.

OPERATION

Leakage

Once the pump is fully primed, no leakage should be visible at pump mating surfaces, or at pump connections or fittings. Keep all line connections and fittings tight to maintain maximum pump efficiency.

Liquid Temperature And Overheating

The maximum liquid temperature for this pump is 160°F (71°C). Do not apply it at a higher operating temperature.
Overheating can occur if operated with the valves in the suction or discharge lines closed. Operating against closed valves could bring the liquid to a boil, build pressure, and cause the pump to rupture or explode. If overheating occurs, stop the pump immediately and allow it to completely cool before servicing it. Approach any over-heated pump cautiously.

**WARNING!**

Allow an over-heated pump to completely cool before servicing. Do not remove plates, covers, gauges, or fittings from an overheated pump. Liquid within the pump can reach boiling temperatures, and vapor pressure within the pump can cause parts being disengaged to be ejected with great force. After the pump cools, drain the liquid from the pump by removing the casing drain plug. Use caution when removing the plug to prevent injury to personnel from hot liquid.

As a safeguard against rupture or explosion due to heat, this pump is equipped with a pressure relief valve which will open if vapor pressure within the pump casing reaches a critical point. If overheating does occur, stop the pump immediately and allow it to cool before servicing it. Approach any over-heated pump cautiously. It is recommended that the pressure relief valve assembly be replaced at each overhaul, or any time the pump casing over-heats and activates the valve. Never replace this valve with a substitute which has not been specified or provided by the Gorman-Rupp Company.

**Strainer Check**

If a suction strainer has been shipped with the pump or installed by the user, check the strainer regularly, and clean it as necessary. The strainer should also be checked if pump flow rate begins to drop. Monitor and record the vacuum suction gauge readings regularly to detect strainer blockage.

Never introduce air or steam pressure into the pump casing or piping to remove a blockage. This could result in personal injury or damage to the equipment. If backflushing is absolutely necessary, liquid pressure must be limited to 50% of the maximum permissible operating pressure shown on the pump performance curve.

**Pump Vacuum Check**

With the pump inoperative, install a vacuum gauge in the system, using pipe dope on the threads. Block the suction line and start the pump. At operating speed the pump should pull a vacuum of 20 inches (508,0 mm) or more of mercury. If it does not, check for air leaks in the seal, gasket, or discharge valve.

Open the suction line, and read the vacuum gauge with the pump primed and at operation speed. Shut off the pump. The vacuum gauge reading will immediately drop proportionate to static suction lift, and should then stabilize. If the vacuum reading falls off rapidly after stabilization, an air leak exists. Before checking for the source of the leak, check the point of installation of the vacuum gauge.

**STOPPING**

Never halt the flow of liquid suddenly. If the liquid being pumped is stopped abruptly, damaging shock waves can be transmitted to the pump and piping system. Close all connecting valves slowly.

On engine driven pumps, reduce the throttle speed slowly and allow the engine to idle briefly before stopping.

**CAUTION**

If the application involves a high discharge head, gradually close the discharge throttling valve before stopping the pump.

**WARNING!**

Do not operate the pump against a closed discharge throttling valve for long periods of time. If operated against
a closed discharge throttling valve, pump components will deteriorate, and the liquid could come to a boil, build pressure, and cause the pump casing to rupture or explode.

After stopping the pump, switch off the engine ignition and remove the key to ensure that the pump will remain inoperative.

PERIODIC CHECKS

Seal Cavity And Bearing Lubrication

Both the seal and bearing cavities were fully lubricated at the factory. Check the lubrication levels before startup, and regularly thereafter as indicated in Section E, Maintenance and Repair. When lubrication is required, use only SAE No. 30 non-detergent oil.

Bearing Temperature Check

Bearings normally run at higher than ambient temperatures because of heat generated by friction. Temperatures up to 160°F (71°C) are considered normal for bearings, and they can operate safely to at least 180°F (82°C).

Checking bearing temperatures by hand is inaccurate. Bearing temperatures can be measured accurately by placing a contact-type thermometer against the housing. Record this temperature for future reference.

A sudden increase in bearing temperatures is a warning that the bearings are at the point of failing to operate properly. Make certain that the bearing lubricant is of the proper viscosity and at the correct level (see LUBRICATION in Section E, Maintenance and Repair). Bearing overheating can also be caused by shaft misalignment and/or excessive vibration.

When pumps are first started, the bearings may seem to run at temperatures above normal. Continued operation should bring the temperatures down to normal levels.

Air Compressor

The air compressor was lubricated for test at the factory. However, always check the lubrication level before startup.

Consult the manual accompanying the air compressor and preform all duties and checks as indicated.

COLD WEATHER PRESERVATION

In below freezing conditions, drain the pump to prevent damage from freezing. Also, clean out any solids by flushing with a hose. Operate the pump for approximately one minute; this will remove any remaining liquid that could freeze the pump rotating parts. If the pump will be idle for more than a few hours, or if it has been pumping liquids containing a large amount of solids, drain the pump, and flush it thoroughly with clean water. To prevent large solids from clogging the drain port and preventing the pump from completely draining, insert a rod or stiff wire in the drain port, and agitate the liquid during the draining process. Clean out any remaining solids by flushing with a hose.
# TROUBLESHOOTING — SECTION D

Review all SAFETY information in Section A.

### WARNING!

Before attempting to open or service the pump:

1. Familiarize yourself with this manual.
2. Lock out or disconnect the power source to ensure that the pump will remain inoperative.
3. Allow the pump to completely cool if overheated.
4. Check the temperature and make sure pump is cool before opening any covers, plates, or plugs.
5. Close the suction and discharge valves.
6. Vent the pump slowly and cautiously.
7. Drain the pump.

**PREVENTIVE MAINTENANCE**

Since pump applications are seldom identical, and pump wear is directly affected by such things as the abrasive qualities, pressure and temperature of the liquid being pumped, this section is intended only to provide general recommendations and practices for preventive maintenance. Regardless of the application however, following a routine preventive maintenance schedule will help assure trouble-free performance and long life from your Gorman-Rupp pump. For specific questions concerning your application, contact your Gorman-Rupp distributor or the Gorman-Rupp Company.

Record keeping is an essential component of a good preventive maintenance program. Changes in suction and discharge gauge readings (if so equipped) between regularly scheduled inspections can indicate problems that can be corrected before system damage or catastrophic failure occurs. The appearance of wearing parts should also be documented at each inspection for comparison as well. Also, if records indicate that a certain part (such as the seal) fails at approximately the same duty cycle, the part can be checked and replaced before failure occurs, reducing unscheduled down time.

For new applications, a first inspection of wearing parts at 250 hours will give insight into the wear rate for your particular application. Subsequent inspections should be performed at the intervals shown on the chart below. Critical applications should be inspected more frequently.

Legend:

I = Inspect, Clean, Adjust, Repair or Replace as Necessary
C = Clean
R = Replace

* Service interval based on an intermittent duty cycle equal to approximately 4000 hours annually. Adjust schedule as required for lower or higher duty cycles or extreme operating conditions.
PUMP MAINTENANCE AND REPAIR – SECTION E

MAINTENANCE AND REPAIR OF THE WEARING PARTS OF THE PUMP WILL MAINTAIN PEAK OPERATING PERFORMANCE.

STANDARD PERFORMANCE FOR PUMP MODEL PAH3A60C-B

* Based on 70°F (21°C) clear water at sea level with minimum suction lift. Since pump installations are seldom identical, your performance may be different due to such factors as viscosity, specific gravity, elevation, temperature, and impeller trim.

If your pump serial number is followed by an “N”, your pump is NOT a standard production model.

Contact the Gorman-Rupp Company to verify performance or part numbers.

CAUTION

Pump speed and operating condition points must be within the continuous performance range shown on the curve.

PUMP AND SEAL DISASSEMBLY AND REASSEMBLY

Review all SAFETY information in Section A.

Follow the instructions on all tags, label and decals attached to the pump.

This pump requires little service due to its rugged, minimum-maintenance design. However, if it becomes necessary to inspect or replace the wearing parts, follow these instructions which are keyed to the illustrations (see Figures 1 through 6) and the corresponding Parts Lists. Maintenance and repair instructions for the air compressor are covered separately in specific literature available from the manufacturer.

Some pump service functions may be performed without separating the pump end assembly from the power source. However, the priming chamber (15, Figure 1) and discharge check valve assembly (23, Figure 1) must be removed to service most pump components. The following instructions assume complete disassembly of the pump is required.

Before attempting to service the pump, shut down the power source and take precautions to ensure that it will remain inoperative. Close all valves in the suction and discharge lines and drain the pump casing by removing the lowermost pipe plug (9, Figure 2). Clean and reinstall the pipe plug.

This pump is designed to handle material which could cause illness through direct exposure or emitted fumes. Wear adequate protective clothing when working on the pump or piping.

Death or serious personal injury and damage to the pump or components can occur if proper lifting procedures are not observed. Make certain that hoists, chains, slings or cables are in good working condition and of sufficient capacity and that they are positioned so that loads will be balanced and the pump or components will not be damaged when lifting. Suction and discharge hoses and piping must be re-
moved from the pump before lifting. Lift the pump or component only as high as necessary and keep personnel away from suspended objects.

Use Only Genuine Gorman—Rupp replacement parts. Failure to do so may create a hazard and damage the pump or diminish optimal pump performance. Any such hazard, damage or diminished performance is not covered by the warranty.

NOTE
When appropriate recycling facilities are available, the user should recycle components and fluids when doing any routine maintenance / repairs and also at the end of the pump’s useful life. All other components and fluids shall be disposed of according to all applicable codes and regulations.

Priming Chamber Removal And Disassembly
(Figure 5)

Disconnect both the suction piping and the air discharge tubing from the priming chamber assembly (1). Support the priming chamber assembly using a sling and a suitable lifting device. Remove the hardware (6 and 7) and separate the priming chamber assembly, gasket (8) and baffle (9) from the pump assembly.

(Figure 6)

Remove the hardware (2 and 3) securing the priming valve (1) to the priming chamber (5). Carefully lift the valve components from the priming chamber. Remove the gasket (4) and clean the mating surfaces.

If the priming valve float is stuck or the strainer (6) is clogged, it can usually be cleaned without further disassembly.

The only serviceable part of the priming valve is the orifice button (not shown). If liquid continues to bypass through the priming chamber after adjusting the orifice button (see Priming Chamber Reassembly and Installation for adjustment), the but-

ton may require replacement. To replace the orifice button, remove one of the “e-clips” from the pivot pin closest to the orifice button and remove the pivot pin. This will allow the linkage to be raised high enough to access the orifice button.

Remove the hex nut and lock washer securing the orifice button to the linkage bar and unscrew the orifice button from the linkage bar.

Discharge Check Valve Removal and Disassembly
(Figure 1)

Remove the hardware (not shown) securing the discharge check valve bracket to the base.

Support the discharge check valve assembly (29) using a sling and a suitable lifting device. Remove the hardware (not shown) and separate the discharge check valve assembly and gasket (not shown) from the pump assembly (1).

The flapper and cover O-ring are the only serviceable parts of the check valve. If the flapper requires replacement, remove the hardware securing the cover. Separate the cover and O-ring and remove the flapper.

Suction Head and Wear Ring Removal
(Figure 2)

The wear ring (4) is easily accessible and may be serviced by removing the suction head (3). Before attempting to service the pump, remove the lower-most pipe plug (8) from the pump casing (7) and drain the pump. Clean and reinstall the drain plug.

It is not necessary to remove the suction spool (18, Figure 1) from the suction head unless replacement of the spool, gasket (25, Figure 1) or suction head is required. To remove the suction spool, disengage the hardware (15 and 16, Figure 1) securing it to the pump casing.

Remove the hardware (1 and 2) and securing the suction head to the pump casing. Install two 5/8—11 UNC-2B capscrews (not supplied) in the tapped holes in the suction head and use the capscrews to press the suction head out of the pump casing. Remove the capscrews from the suction head.
Remove and discard the O-ring (5).

Inspect the wear ring and, if replacement is required, install two 3/4—10 UNC-2B capscrews (not supplied) in the tapped holes in the suction head and use the screws to press the wear ring out of the suction head. Remove the capscrews from the suction head.

**Pump Casing Removal**

(Figure 2)

Remove the uppermost pipe plug (9) from the pump casing and install a lifting eye in the hole. Be sure to screw the lifting eye tightly into the hole as far as it will go. Attach a sling and suitable lifting device to the lifting eye and support the pump casing.

Remove the hardware (1A and 2A) and use the lifting device to pull the pump casing straight away from the rotating assembly (10).

Remove and discard the pump casing O-ring (5A).

**Draining Oil From Seal Cavity**

(Figure 3)

If any further disassembly is to be performed on the pump, the seal oil cavity must be drained to prevent the oil in the seal cavity from escaping as the pump casing is removed.

Position a clean container under the seal cavity drain plug (15B). Remove the plug and drain the oil from the seal cavity into the container. For shorter drain time, remove the air vent (12). Clean and reinstall the drain plug and air vent. Inspect the oil for water, dirt or a cloudy condition which could indicate seal failure.

**Impeller Removal**

(Figure 3)

With the pump casing removed, use an impact wrench with a hex key to loosen the impeller capscrew (1). Remove the capscrew, impeller washer (2) and roll pin (3).

Use a suitable three-jawed puller to remove the impeller (4) and key (26) from the shaft (25). Use caution when removing the impeller; tension on the shaft seal spring will be released as the impeller is removed.

**NOTE**

An alternate method of removing the impeller is to insert a pair of wedges 180° apart between the impeller and seal plate (10). Tap the wedges evenly in an alternating pattern to "walk" the impeller off the shaft.

Remove the impeller adjusting shims (5); tie and tag the shims, or measure and record their thickness for ease of reassembly.

Inspect the impeller and replace if cracked or badly worn.

**Seal Removal**

(Figures 3 and 8)

Remove the spring centering washer and seal spring. Slide the shaft sleeve (7) and rotating portion of the seal off the shaft as a unit.

Apply oil to the shaft sleeve and work it up under the rubber bellows. Slide the rotating portion of the seal off the shaft sleeve. Remove the shaft sleeve O-ring (8).

Use a pair of stiff wires with hooked ends to remove the stationary element from the seal plate bore.

An alternate method of removing the stationary seal components is to remove the hardware (16 and 17) and separate the seal plate and gasket (14) from the pedestal (18). Position the seal plate on a flat surface with the impeller side down. Use a wooden dowel or other suitable tool to press on the back side of the stationary element until the element and its O-ring can be removed.

If no further disassembly is required, refer to Seal Installation.

**Separating Rotating Assembly From Power Source**

(Figure 1)

Further disassembly requires separating the rotating assembly from the power source. Remove the coupling securing the rotating assembly to the power source and remove the key (28, Figure 3).
Remove the hardware (6, 7 and 8) securing the air compressor (11) to the bearing cap (20, Figure 3). Use a pry bar to raise the air compressor enough to remove the spacers (2). Remove the belt (6) from the sprocket (3). Use a sling and suitable lifting device to remove the air compressor.

Remove any hardware (15, 16, 20 and 39) securing the rotating assembly to the bearing stand (28). Remove the hardware securing the guard (10) to the bearing cap and use a suitable hoist and sling to move the rotating assembly to a clean, well-equipped workshop for further disassembly.

Remove the capscrews from the center of the sprocket (4). Reinstall the capscrews in the tapped holes in the bushing and tighten them in an alternating pattern until the bushing is “jacked” out of the sprocket (3). Slide the bushing and sprocket off the shaft. Remove the key (5).

Shaft and Bearing Removal and Disassembly
(Figure 3)

When the pump is properly operated and maintained, the pedestal (18) should not require disassembly. Disassemble the shaft and bearings only when there is evidence of wear or damage.

CAUTION
Shaft and bearing disassembly in the field is not recommended. These operations should be performed only in a properly equipped shop by qualified personnel.

Remove the pedestal drain plug (15A) and drain the lubricant. Clean and reinstall the drain plug. For shorter drain time, remove the air vent (12A). Clean and reinstall the drain plug and air vent after draining.

If not removed with the seal assembly, remove the hardware (16 and 17) and separate the seal plate (10) and gasket (14) from the pedestal.

Disengage the hardware (16A and 17A) and remove the drive flange (20), gasket (21) and oil seal (19). Press the oil seal from the drive flange.

Place a block of wood against the impeller end of the shaft (25) and tap the shaft and assembled bearings (24 and 27) from the pedestal.

Press the oil seals (13 and 13A) from the pedestal.

After removing the shaft and bearings, clean and inspect the bearings in place as follows.

CAUTION
To prevent damage during removal from the shaft, it is recommended that bearings be cleaned and inspected in place. It is strongly recommended that the bearings be replaced any time the shaft and bearings are removed.

Clean the pedestal, shaft and all component parts (except the bearings) with a soft cloth soaked in cleaning solvent. Inspect the parts for wear or damage and replace as necessary.

WARNING!
Most cleaning solvents are toxic and flammable. Use them only in a well ventilated area free from excessive heat, sparks, and flame. Read and follow all precautions printed on solvent containers.

Clean the bearings thoroughly in fresh cleaning solvent. Dry the bearings with filtered compressed air and coat with light oil.

CAUTION
Bearings must be kept free of all dirt and foreign material. Failure to do so will greatly shorten bearing life. Do not spin dry bearings. This may scratch the balls or races and cause premature bearing failure.

Rotate the bearings by hand to check for roughness or binding and inspect the bearing rollers and balls. If rotation is rough or the rollers or bearing balls are discolored, replace the bearings.
The bearing tolerances provide a tight press fit onto the shaft and a snug slip fit into the pedestal. Replace the bearings, shaft, or pedestal if the proper bearing fit is not achieved.

If bearing replacement is required, straighten the tab on the bearing lock washer (23). Use a spanner wrench to remove the bearing lock nut (22). Remove the bearing lock washer.

Use a bearing puller to remove the inboard and outboard bearings from the shaft.

**Shaft and Bearing Reassembly and Installation** *(Figure 3)*

Inspect the shaft (25) for distortion, nicks or scratches, or for thread damage on the impeller end. Dress small nicks and burrs with a fine file or emery cloth. Replace the shaft if defective.

Clean and inspect the bearings as indicated in *Shaft And Bearing Removal And Disassembly.*

**CAUTION**

To prevent damage during removal from the shaft, it is recommended that bearings be cleaned and inspected in place. It is strongly recommended that the bearings be replaced any time the shaft and bearings are removed.

The bearings may be heated to ease installation. An induction heater, hot oil bath, electric oven, or hot plate may be used to heat the bearings. Bearings should never be heated with a direct flame or directly on a hot plate.

**NOTE**

*If a hot oil bath is used to heat the bearings, both the oil and the container must be absolutely clean. If the oil has been previously used, it must be thoroughly filtered.*

**NOTE**

Position the outboard bearing (24) on the shaft with the retaining ring on the bearing O.D. toward the drive end of the shaft.

Heat the bearings to a uniform temperature no higher than 250°F (120°C), and slide the bearings onto the shaft, one at a time, until they are fully seated against the shaft shoulders. This should be done quickly, in one continuous motion, to prevent the bearings from cooling and sticking on the shaft.

After the bearings have been installed and allowed to cool, check to ensure that they have not moved during cooling. If movement has occurred, use a suitably sized sleeve and a press to reposition the bearings against the shaft shoulders.

If heating the bearings is not practical, use a suitably sized sleeve and an arbor (or hydraulic) press to install the bearings on the shaft.

**CAUTION**

When installing the bearings onto the shaft, never press or hit against the outer race, balls, rollers or cage. Press only on the inner race.

**CAUTION**

It is recommended that a new bearing lock washer (23) be installed any time the shaft and bearings are disassembled. Re-use of an old lock washer may create a pre-load condition on the bearing, resulting in premature bearing failure.

Install the bearing lockwasher (23) and screw the bearing locknut (22) onto the shaft until tight. Torque the bearing lock nut to (150 ft. lbs. (20,8 m. kg.). After torquing, locate the tab on the lock washer that aligns with a slot in the lock nut and bend the tab over into the slot.

Apply a light coating of oil to the lip of the inboard oil seal (13) and press it into the pedestal bore with the lip positioned as shown in Figure 3. Press the oil seal into the pedestal until the face is just flush with the machined surface on the inside of the pedestal.

It is recommended that a sleeve be positioned against the inboard oil seal to prevent the lip of the oil seal from rolling as the shaft and bearings are installed in the pedestal. The O.D. of the sleeve
should be just smaller than the pedestal bore, while the I.D. of the sleeve should be just larger than the O.D. of the oil seal area of the shaft.

With the oil seal sleeve in place, lubricate the oil seal area of the shaft and slide the shaft and assembled bearings into the pedestal until the retaining ring on the outboard bearing seats against the pedestal. Remove the oil seal sleeve.

**CAUTION**

When installing the shaft and bearings into the bearing bore, push against the outer race. **Never** hit the balls, rollers or cages.

Apply a light coating of oil to the lip of the outboard oil seal (13A) and press it into the pedestal with the lip positioned as shown in Figure 3. The face of the oil seal should be **just flush** with the outer face of the pedestal.

Apply a light coating of oil to the lip of the oil seal (19) and press it into the drive flange (20) with the lip positioned as shown in Figure 3. The oil seal should be centered in the flange bore.

Install the gasket (21). Apply “Loctite Threadlocker No. 242” or equivalent compound to the cap-screws (17A) and secure the bearing cap to the pedestal with the hardware (16A and 17A). Torque the cap-screws (17A) in a criss-cross pattern to 80 ft. lbs. (11 m. kg.). Torque the cap-screws again in a criss-cross pattern to 110 ft. lbs. (15 m. kg.), going around the bolt circle 1-1/2 times.

Lubricate the bearings as indicated in **LUBRICATION** at the end of this section.

**Securing Rotating Assembly to Power Source**

(Figure 1)

Install the key (5) in the shaft keyway, making sure to leave room in the keyway for the drive key (28, Figure 3). Install the bushing (7) and sprocket (6) on the shaft to the dimension shown in Figure 7.
seat bore in the seal plate for dirt, nicks and burrs, and remove any that exist. The stationary seat bore must be completely clean before installing the seal.

**CAUTION**

A new seal assembly should be installed any time the old seal is removed from the pump. Wear patterns on the finished faces cannot be realigned during reassembly. Reusing an old seal could result in premature failure.

To ease installation of the seal, lubricate the shaft sleeve O-ring and the stationary element O-ring with a very small amount of light lubricating oil. See Figure 8 for seal part identification.

![Figure 8. Seal Assembly](image)

**CAUTION**

This seal is not designed for operation at temperatures above 160°F (71°C). Do not use at higher operating temperatures.

If the seal plate was removed, install the seal plate gasket (14). Position the seal plate over the shaft and secure it to the pedestal with the hardware (16 and 17).

Press the stationary element and its O-ring into the seal plate until fully seated in the seal plate bore. A push tube cut from a length of plastic pipe would aid this process. The I.D. of the tube should be slightly larger than the O.D. of the shaft sleeve (7).

Install the shaft sleeve O-ring (8) in the groove in the I.D. of the sleeve. Lubricate the O-ring and the O.D. of the shaft sleeve with “P−80® Emulsion” or water. Do not use oil or any substitute lubricant other than water.

Slide the rotating subassembly (consisting of the rotating element, retainer and bellows) onto the sleeve until the rotating element is just flush with the chamfered end of the sleeve. Slide the shaft sleeve and rotating subassembly onto the shaft until the seal faces contact and the shaft sleeve...
seats against the shoulder on the impeller shaft. Install the seal spring and spring centering washer.

Lubricate the seal assembly as indicated in LUBRICATION, after the impeller has been installed.

**Impeller Installation And Adjustment**  
*(Figure 5)*

Inspect the impeller (4) and replace it if cracked or badly worn.

Install the same thickness of adjusting shims (5) as previously installed. Install the impeller key (26) in the shaft keyway. Align the keyway in the impeller with the shaft key and press the impeller onto the shaft until fully seated.

A clearance of .025 to .040 inch (0.64 to 1.02 mm) between the impeller and the seal plate is necessary for maximum pump efficiency. Measure this clearance and add or remove impeller adjusting shims as required.

Apply ‘Loctite Retaining Compound No. 242’ or equivalent to the threads of the impeller capscrew (2). Install the roll pin (4) in the hole in the impeller. Position the impeller washer over the end of the impeller shaft so the hole in the washer aligns with the roll pin. Use a strap wrench to block impeller rotation and torque the impeller capscrew to 180 ft. lbs. (24.9 m. kg.).

**Pump Casing Installation**  
*(Figure 2)*

Lubricate the O-ring (5A) with light grease and install it in the groove in the O.D. of the seal plate (10, Figure 3). Install a lifting eye in the uppermost hole in the pump casing (1) for the pipe plug (9). Be sure to screw the lifting eye tightly into the hole as far as it will go. Attach a sling and suitable lifting device to the lifting eye and use the lifting device to position the pump casing over the rotating assembly. Install the hardware (1 and 2) on the studs (7A) and use the hardware to fully seat the pump casing against the seal plate. Remove the lifting eye and reinstall the pipe plug.

**Suction Head and Wear Ring Installation**  
*(Figure 2)*

If the wear ring (4) was removed, position the replacement wear ring in the suction head (3) and use an arbor (or hydraulic) press to press it into the suction head until fully seated.

Install the O-ring (5) in the groove in the O.D. of the suction head and lubricate it with light grease. Position the suction head over the studs (7) and use the hardware (1 and 2) to fully seat the suction head in the pump casing.

See Figure 1. If the suction spool (18) was removed, install a new gasket (25) and secure the spool to the suction head with the previously removed hardware (15 and 16).

**Discharge Check Valve Reassembly and Installation**  
*(Figure 1)*

If the discharge check valve (29) was disassembled to replace the flapper or cover O-ring, position the flapper in the valve body and check to ensure free movement.

Install the valve cover O-ring and secure the cover to the body with the previously removed hardware.

Apply a small amount of light grease to the discharge flange gasket to hold it in place and position it against the pump casing flange. Support the discharge check valve assembly using a sling and a suitable lifting device. Using the previously removed hardware, secure the discharge check valve assembly and flange gasket to the pump assembly (1).

** Priming Chamber Assembly and Installation**  
*(Figure 6)*

Clean and inspect the components of the priming valve (1). Inspect the linkage and ensure the orifice button (not shown) squarely engages the valve seat. Replace the orifice button if required (see Priming Chamber Removal and Disassembly for orifice button removal).

If the orifice button was removed, screw the new orifice button into the linkage bar until fully seated.
Align the hole in the linkage bar with the holes in the bracket and reinstall the pivot pin. Secure the pivot pin with the previously removed "e-clip".

Adjust the orifice button seating as necessary by screwing the orifice button into or out of the linkage bar. Proper adjustment is achieved when the orifice button fully seats against the orifice before the linkage bar on the float bottoms against the threads on the orifice button. When adjustment is complete, install and tighten the lock washer and hex nut securing the orifice button.

Install the strainer (6) and priming valve gasket (4).

Lower the float into the priming chamber (5) and secure the priming valve with the previously removed hardware (2 and 3).

(Figure 5)

Install the baffle (9) and gasket (8) and use a sling and suitable lifting device to position the priming chamber assembly on the hopper spool (18, Figure 1). Secure the priming chamber assembly with the hardware (6 and 7).

Reconnect the suction piping to the hopper spool and the air discharge tubing to the priming chamber assembly.

**LUBRICATION**

(Figure 3)

**Seal Assembly**

Before starting the pump, remove the air vent (12) and fill the seal cavity with approximately 5 quarts (4.7 liters) of SAE No. 30 non-detergent oil or to the center of the sight gauges (9). Clean and reinstall the vented plug. Maintain the oil level at the middle of the sight gauges.

**Bearings**

(Figure 3)

The bearing housing was fully lubricated when shipped from the factory. Check the oil level regularly through the sight gauges (9A) and maintain it at the midpoint of the gauges. When lubrication is required, remove the air vent (12A) and add SAE No. 30 non-detergent oil through the opening. When lubricating a dry (overhauled) intermediate, fill the bearing cavity with approximately 50 ounces (1.5 liter) of oil. Clean and reinstall the air vent. Do not over-lubricate. Over-lubrication can cause the bearings to over-heat, resulting in premature bearing failure.

Under normal conditions, drain the bearing housing once each year and refill with clean oil. Change the oil more frequently if the pump is operated continuously or installed in an environment with rapid temperature change.

**CAUTION**

Monitor the condition of the bearing lubricant regularly for evidence of rust or moisture condensation. This is especially important in areas where variable hot and cold temperatures are common.

For cold weather operation, consult the factory or a lubricant supplier for the recommended grade of oil.

**Power Source**

Consult the literature supplied with the power source, or contact your local power source representative.
